SERIE Documentos de Trabajo 10/2013
SUSTAINABILITY OF EXTERNAL IMBALANCES IN THE OECD COUNTRIES*

ABSTRACT
In this paper, we provide a test of the sustainability of external imbalances in the OECD countries over the years 1970-2007, i.e., before the beginning of the international financial crisis. Specifically, we deal with the case of those countries that have experienced current account deficits in more than half of the years throughout the period of analysis, and address the recent critique of Bohn (2007) on unit root and cointegration tests of the intertemporal budget constraint.

Key words: External imbalances, Sustainability, Current account.

RESUMEN
En este artículo, ofrecemos un test de la sostenibilidad de los desequilibrios exteriores en los países de la OCDE durante los años 1970-2007, es decir, antes del inicio de la crisis financiera internacional. En concreto, nos ocupamos del caso de aquellos países que han experimentado un déficit por cuenta corriente en más de la mitad de los años de todo el periodo de análisis, y abordar la reciente crítica de Bohn (2007) sobre la raíz unitaria y tests de cointegración de la restricción presupuestaria intertemporal.

Palabras clave: Desequilibrios externos, sostenibilidad, cuenta corriente.

1. INTRODUCTION

Global external imbalances seem nowadays to be quite different as compared to those prevailing in the past. First, they mostly affect rich countries, both the US and within the euro area. In addition, they are primarily driven by private saving and investment decisions, rather than by government deficits. Moreover, these imbalances are financed in a more orthodox way (i.e., through either direct or portfolio investment), rather than through bank lending. Accordingly, these imbalances are a matter of concern for such countries, requiring an adequate policy answer (Blanchard, 2007).

The problem of global external disequilibria relates in turn to the current international financial crisis, as discussed at length in Obstfeld and Rogoff (2010). Regarding the case of the European Union (EU), those countries with the highest current account disequilibria are those that have experienced a greater fall in their levels of domestic demand (Lane, 2010). Moreover, it has been argued that for these countries, usually the eurozone members with lower income levels, borrowing in international markets would have become easier before the beginning of the crisis. In fact, the greater financial integration, together with the adoption of the euro, would have meant a reduction in the cost of capital and the disappearance of exchange rate risk. As a result, this would have translated into both a decrease in saving and an increase in investment, and hence into a deterioration of the current account balance (Blanchard and Giavazzi, 2002). Even more, the prospects of convergence as regards the richer countries would have favour growth expectations in those countries, which contributed additionally to greater deficits; see Lane (2010). However, unlike the case of the US, where the size of the external deficit has led to a wide academic debate [see, e.g., Mann (2002), Blanchard, Giavazzi and Sa (2005), Edwards (2005) or Obstfeld and Rogoff (2007)], this has not been the norm in the European case, with a predominance of descriptive studies of a limited analytical content.

The usual way to analyzing current account imbalances makes use of the intertemporal approach to the current account (Sachs, 1981; Obstfeld and Rogoff, 1995; Razin, 1995). According to this approach, given that, from the perspective of the national accounts, the current account equals the difference between savings and investment, and, because savings and investment decisions are based on intertemporal factors (such as life-cycle features, the expected returns of investment projects, and the like) the current account is necessarily an intertemporal phenomenon.

In an important contribution, Milesi-Ferretti and Razin (1996) discuss the usual notion of sustainability in relation to the country’s intertemporal solvency, that is, when the present discounted value of
future trade surpluses equals current external indebtedness. Put in other words, current account sustainability would be defined as the ability of an economy of satisfying its intertemporal constraint in the long run, in absence of a drastic change either in the behaviour of the private sector or in economic policy (Taylor, 2002). In general, a current account deficit in excess of 5% of GDP is regarded as unsustainable, so that above this threshold the adjustment process of the current account usually begins (Freund, 2005).

Traditional analyses of current account sustainability are based on unit root and cointegration tests of the intertemporal budget constraint. A first contribution was Trehan and Walsh (1991), who tested for the stationarity of the external investment position of the United States during 1946-1987 to find it was stationary, so that US external imbalances would have been sustainable. However, Husted (1992) obtained no cointegration between the US exports and imports series along the period 1967-1989; the external deficit had been sustainable only after considering a structural change at the end of 1983. By focusing instead on the trade balance and foreign indebtedness (rather than exports and imports), Wickens and Uctum (1993) found sustainability of the US external imbalances for the period 1970-1988. Wu, Fountas and Chen (1996) analyzed cointegration between exports and imports for the US and Canada throughout 1973-1994, and concluded there was no sustainability. On the contrary, Apergis, Katrakilidis and Tabakis (2000) found that the current account had been sustainable in the case of Greece, along the period 1960-1994. In turn, Liu and Tanner (1996) performed stationarity tests on the current accounts of 7 industrialized countries between 1970-1990, finding sustainability in two cases (France and Italy), but not for the other five (US, Germany, Japan, UK and Canada); however, when a discrete break in the current account process was included, sustainability appeared for the US, Germany and Japan.

Other more recent contributions apply the unit root and cointegration tests in a panel data context. Wu (2000) performed panel unit root tests on the current accounts of 10 OECD countries between 1977 and 1997, and found sustainability of their external imbalances. Also, using panel cointegration tests on exports and imports, Wu, Chen and Lee (2001) found external sustainability for 7 industrialized countries from 1973 to 1998. However, following this methodology but identifying which members from within the panel exhibit current account sustainability for a sample of 11 OECD countries and the period 1980-2002, Holmes (2006) was able to distinguish between six countries that exhibited sustainability (Australia, Belgium, Canada, Japan, the UK and the US), and five others that did not offer evidence in favour of sustainability (France, Germany, Italy, Norway and Spain). Finally, in a recent study for a group of 23 OECD countries over the period 1970-2012, Camarero, Carrion-i-Silvestre and Tamarit (2013) tested for external sustainability using several types of cointegration and multicointegration tests. Their results pointed to the existence of weak
sustainability for all the countries in the sample when considering the
traditional flow approach to the external intertemporal budget
constraint. However, when applying a stock-flow approach, some
dergree of strong sustainability was found for up to six countries,
namely, Japan, New Zealand, Austria, the Netherlands, Portugal and
Spain.

As can be seen, the available results on the sustainability of external
imbalances are not always clear-cut, which can be due to differences on
methodology, the country data set, and the time period under analysis.
However, traditional analyses of sustainability (for either the public
deficit or the external deficit) have been recently criticized by Bohn
(2007). According to this author, these tests, based on unit root and
cointegration tests of the (government’s or nation’s) intertemporal
budget constraint, are incapable of rejecting the existence of
sustainability. In place of the traditional method, Bohn proposes an
alternative approach, based on the existence of an arbitrarily high order
of integration of the variables involved, and on error-correction-type
policy reaction functions. Moreover, this previous literature (with the
only exception of Camarero et al., 2013) neglects the role of capital
gains or losses on net foreign asset positions. According to Gourinchas
and Rey (2007), for a country facing an external disequilibrium,
adjustment through future trade surpluses (the so called “trade
channel”, i.e., that stressed by the intertemporal approach to the
current account) will be complemented by changes in the returns on
domestic assets held by foreigners relative to the return on foreign
assets held by domestic residents. The latter effect (the so called
“valuation channel”) may occur in turn via a depreciation of the
domestic currency.

Notice that Bohn’s (2007) methodology has been already applied by
Durdu, Mendoza and Terrones (2013) to a panel of 50 countries (21
industrial and 29 emerging) over the period 1970-2006. Unlike these
authors, in this paper we will only analyze developed countries
experiencing external deficits, and on a country-by-country basis; see
below for details.

Therefore, in this paper we will use Bohn’s approach to assess the
sustainability of external imbalances in those OECD countries
experiencing current account deficits in more than half of the years
along the period 1970-2007, i.e., before the beginning of the crisis,
allowing for the valuation effects emphasized by Gourinchas and Rey.
The paper is organized as follows. In section 2, we describe the
underlying theoretical framework. Next, in section 3 we introduce the
empirical methodology, and discuss the data and the empirical results.
The main conclusions are summarized in section 4.
2. THEORETICAL FRAMEWORK

The sustainability of external deficits is a matter of concern for governments, and is related to the issue of long-run solvency. A current account deficit is regarded as sustainable when, if maintained in the indefinite future, it does not violate the nation’s solvency constraint; and a nation is said to be solvent if the present-value budget constraint, i.e., its intertemporal budget constraint (IBC) holds. In other words, a deficit can be sustainable if the country can borrow. However, if the interest rate on the external debt exceeds the growth rate of the economy, debt dynamics would lead to an ever-increasing ratio of debt to GDP. The dynamics of debt accumulation could be stopped only if the ratio of the external deficit to GDP would turn to be a surplus.

The customary approach for analyzing external imbalances is based on the intertemporal approach to the current account. Under this approach, the current account (i.e., changes in a country’s net indebtedness) is considered as an intertemporal issue, since decisions on indebtedness imply changes in future consumption possibilities and these are based on expectations of the entire future path of a number of variables. The intertemporal model of the current account originates in the work of, among others, Sachs (1981, 1982), Obstfeld (1982), and Svensson and Razin (1983); some overviews are provided in Obstfeld and Rogoff (1995) and Razin (1995).

We start with some accounting identities. In period $t$, the current account, i.e., the change in net foreign assets vis-à-vis the rest of the world, equals net exports of goods and services plus net factor payments from abroad:

$$\Delta NFA_t = CA_t = NX_t + rNFA_{t-1}$$

(1)

where $CA$, $NFA$ and $NX$ stand for the current account, net foreign assets and net exports, respectively, all of them in real terms, and $r$ is a (constant) real interest rate. Notice that when $NFA > 0$ the country is a net creditor, and when $NFA < 0$ the country is a net debtor. Alternatively:

$$\Delta NFA_t = CA_t = Q_t + rNFA_{t-1} - (C + I + S - I)$$

(2)

where $Q$ is gross domestic product (GDP, so $Q + rNFA_{t-1}$ is gross national product), and $C$, $S$ and $I$ denote total (i.e., private plus public) consumption, saving and investment, respectively. As can be seen,

---

1 Notice that we are omitting here unilateral transfers, usually a small item in the balance of payments. Alternatively, net exports could be assumed net of transfers.
equation (2) links the current account balance with decisions on saving and investment. Since (1) holds every period, solving for \( NFA_t \) and iterating forward over an infinite horizon yields the nation’s IBC, written in terms of GDP shares:

\[
nfa_t = -\sum_{j=0}^{\infty} \left( \frac{1 + g}{1 + r} \right)^j E_t \cdot nx_{t+j+1} \cdot \lim_{j \to \infty} \frac{1 + g}{1 + r} \cdot E_t \cdot nfa_{t+j+1}
\]

(3)

where \( nfa \) and \( nx \) denote, respectively, net foreign assets and net exports, both as ratios to GDP; \( E \) is the expectations operator; and \( g \) stands for the rate of growth of real GDP, assumed (as the real interest rate) to be constant for simplicity. The condition for current account sustainability is:

\[
\lim_{j \to \infty} \left( \frac{1 + g}{1 + r} \right)^j \cdot E_t \cdot nfa_{t+j+1} = 0
\]

(4)

i.e., the transversality condition; or, equivalently:

\[
nfa_t = -\sum_{j=0}^{\infty} \left( \frac{1 + g}{1 + r} \right)^j E_t \cdot nx_{t+j+1}
\]

(5)

By multiplying both sides of (5) by \(-1\), so that the country is a net debtor, we can see that solvency requires that the country must run expected future trade surpluses equal, in present-value terms, to the current value of its outstanding net liabilities vis-à-vis the rest of the world.

The standard approach to test for sustainability of the current account consists of estimating a cointegration relationship between net exports and the (lagged) level of net foreign assets, both as ratios to GDP:

\[
x_t = \alpha + \beta nfa_{t-1} + \nu_t
\]

(6)

where \( \nu_t \) denotes an error term. In this equation, a negative and significant estimate of \( \beta \) would be a sufficient condition for solvency, indicating that the nation satisfies its present-value budget constraint.

Testing whether \( \beta < 0 \) from the estimation of (6) or, alternatively, whether \( \beta' = 1 \) from the estimation of a cointegration relationship such as:

\[
exp_t = \alpha' + \beta'imp_t + \nu_t
\]

(7)

where \( exp \) and \( imp \) denote, respectively, the GDP ratios of the exports of goods and services, and the imports of goods and services plus net interest payments and net transfer payments, and \( \nu_t \) is an error term, are customary approaches to test for the sustainability of external imbalances.
However, this kind of assessments of external sustainability based on unit root and cointegration tests have been recently criticized by Bohn (2007), on the grounds that such tests are incapable of rejecting sustainability. Specifically, Bohn derives the following three propositions, related to the order of integration of net foreign assets, net exports, exports, and imports, in order to verify under which conditions the transversality condition and the IBC hold (see Bohn (2007) for details):

(i) If $nfa_t$ is integrated of order $m$ for any finite $m \geq 0$, then $nfa_t$ satisfies the transversality condition, and $nfa_t$ and $nx_t$ satisfy the IBC.

(ii) If $exp_t$ and $imp_t$ are integrated of order $m_X$ and $m_M$, respectively, where $\Delta nfa_t = exp_t - imp_t$; then $nfa_t$ is integrated of order $m$ with $m \leq \max(m_X, m_M) + 1$, so the transversality condition and the IBC hold.

(iii) If $nfa_t$ and $nx_t$ follow an error-correction specification of the form $nx_t + \rho nfa_{t-1} = z_t$, and $z_t$ is integrated of order $m$ for some $\rho < 0$ such that $|\rho| < 0.1 + r^-$, where $r$ is a constant interest rate, then $nfa_t$ satisfies the transversality condition and the IBC holds.

Notice, on the other hand, that these are just sufficient conditions, so that a failure of the tests would not mean a rejection of sustainability.

3. DATA AND EMPIRICAL RESULTS

In this section, we provide a test of Bohn’s three propositions for the case of the sustainability of current account imbalances in the OECD countries. We use data on net exports and net foreign assets, as well as on exports and imports of goods and services (the latter augmented with net interest payments and net transfer payments), all of them as percentages of GDP, for those OECD countries experiencing current account deficits in more than half of the years along our sample period.

These countries are Australia, Austria, Canada, Greece, Ireland, Italy, New Zealand, Portugal, Spain, the UK, and the US. The data are annual, and have been taken from the International Monetary Fund’s International Financial Statistics. In turn, the net foreign asset positions come from the updated and extended version of the External Wealth of Nations Mark II database developed by Lane and Milesi-Ferretti (2007), which includes the valuation effects mentioned above. The sample period runs from 1970 to 2007, i.e., the last year before the beginning of the international financial crisis. Notice that using data from 2008 on would tend to bias the results, given that external imbalances have been reduced to a significant extent since the onset of the crisis. This has been especially true in those countries whose pre-crisis current
account balances were in excess of what could be explained by standard economic fundamentals (Lane and Milesi-Ferretti, 2012).

In a related paper, Durdu, Mendoza and Terrones (2013) analyze the sustainability of external imbalances, using a panel of 50 countries (21 industrial and 29 emerging) over the period 1970-2006. In this paper, however, we will focus only on those countries experiencing external deficits, since sustainability should apply to deficits rather than surpluses, for the case of industrial countries. In addition, we will perform the analysis on a country-by-country basis, since panel estimation can hide the different behaviour of specific countries regarding sustainability of their external imbalances.

We begin by testing for the order of integration of the variables nfa_t, exp_t and imp_t. However, as is well known, misspecification errors due to the non-consideration of structural breaks can bias the analysis under the standard Dickey-Fuller test statistics for a unit root. In order to avoid this pitfall, we will first run a test to assess whether a structural break is present or not in three time series. We have used the Perron and Yabu (2009) test for structural changes in the deterministic components of a univariate time series when it is a priori unknown whether the series is trend-stationary (i.e., the I(0) case) or contains an autoregressive unit root (i.e., the I(1) case). The Perron and Yabu test statistic, called Exp-WFS, is based on a quasi-Feasible Generalized Least Squares approach using an autoregression for the noise component, with a truncation to 1 when the sum of the autoregressive coefficients is in some neighbourhood of 1, along with a bias correction. For given break dates, Perron and Yabu (2009) propose an F-test for the null hypothesis of no structural change in the deterministic components using the Exp functional developed in Andrews and Ploberger (1994).

The specification chosen to test for the presence of a structural break in our three variables is given by Model III in Perron and Yabu (2009), which consider that the structural break may affect both the level and the slope of the time trend. According to the results of the Exp-WFS test presented in Table 1, the null hypothesis of absence of a structural break is rejected at the 5% level of statistical significance for some of the variables (namely, exp for Austria; nfa_t, exp_t and imp_t for Canada; nfa_t and exp for Greece and Ireland; nfa_t and imp_t for Spain; and nfa_t for the UK), while it cannot be rejected for the rest of variables. Consequently, the analysis of the order of integration has to consider the presence of structural breaks for the first group of variables, while for the second group we will use standard unit root tests with no structural changes.

Notes:
* denotes significance at the 5% level. The critical values are taken from Perron and Yabu (2009), Table 2.c.
A trimming parameter ε = 0.15 has been used for the applications.

First, regarding the analysis of the order of integration when structural changes are present, we have used the GLS-based unit root test statistics proposed in Kim and Perron (2009) and extended in Carrion-i-Silvestre, Kim and Perron (2009). This approach allows for multiple breaks at an unknown time under both the null and alternative hypotheses, unlike the previously used tests (e.g., Zivot and Andrews,
1992; Perron and Vogelsang, 1992; or Perron, 1997), which assumed that if a break occurred it did so only under the alternative hypothesis of stationarity. The results of applying the Carrion-i-Silvestre-Kim-Perron tests, allowing up to three breaks, are shown in Table 2; the estimated break dates appear in the last column. In general, the break dates are concentrated in the first 1980s (Austria, Greece, Spain), and at the end of this decade (Canada, Ireland, UK). As can seen, the null hypothesis of a unit root with structural breaks cannot be rejected for all series at the 5% level of significance. Accordingly, we can conclude that the variables in Table 2 are I(1) with a structural break.

Notes:  
∗ denotes significance at the 5% level. The critical values were obtained from simulations using 1,000 steps to approximate the Wiener process and 10,000 replications.  
Note that for the MSB and MP^GLS_β tests the null hypothesis is rejected in favour of stationarity when the estimated value is smaller than the critical value.

Second, for the analysis of the order of integration when a structural change is not present, we have used a modified version of the tests of Phillips and Perron (1988) proposed by Ng and Perron (2001), which try to solve the main problems present in these conventional tests for unit roots. This method consists of a class of modified tests, called M^GLS_t, originally developed in Stock (1999) as M-tests, and computed after detrending the series under analysis using the method of Generalized Least Squares (GLS) as proposed in Elliott, Rothenberg and Stock (1996). Such modifications improve the tests with regard to both size distortions and power. According to the results in Table 3, the null hypothesis of non stationarity cannot be rejected in all cases at the 5%
level of significance, except for the variable \( \text{imp}_t \) for Australia where it would be rejected at the 10% level. Therefore, with the only possible exception of \( \text{imp}_t \) for Australia, we can conclude that the variables in Table 3 are I(1) without a structural break.

</table>

Notes: ‘*’ and ‘**’ denote significance at the 5% and 10% levels, respectively. The critical values are taken from Ng and Perron (2001), Table I. The autoregressive truncation lag has been selected using the modified Akaike information criterion, as proposed by Perron and Ng (1996).

Hence, from the results in tables 1 to 3, and with the only possible exception of \( \text{imp}_t \) for Australia, the three series would be concluded to be non-stationary (with or without a structural break, depending on each particular case), and the first two propositions of Bohn (2007) would hold.

Next, we estimate, using the method of Non-Linear Least Squares, the error-correction specification analogue to (6):

\[
\Delta \text{nx}_t = \omega + \delta(L)\Delta \text{nfa}_{t-1} + \rho(\text{nx}_{t-1} - \alpha - \beta \text{nfa}_{t-2}) + \gamma(L)\Delta \text{nx}_{t-1} + \eta_t \tag{8}
\]
where η_t is an error term, and the results are shown in Table 4. As can be seen, the error-correction coefficient ρ always shows the expected negative sign, and is significant at the conventional levels in all cases with the only exception of Ireland, where significance only appears at the 15% level. Regarding the long-run coefficient β, we find:

- a negative and statistically significant coefficient for Austria, Canada, Italy, and New Zealand
- a positive and statistically significant coefficient for Australia, Portugal, Spain, and the US
- a non significant coefficient for Greece, Ireland, and the UK

**Notes:**
(i) t-statistics in parentheses.
(ii) †, *, and ** denote significance at the 1%, 5% and 10% levels, respectively.

Hence, the third proposition of Bohn (2007) would hold, and the current account deficit would be sustainable, only for the cases of Austria, Canada, Italy, and New Zealand. In particular, the adjustment of the net exports-GDP ratio to a given change in the net foreign assets-GDP
ratio would have had an average half-life of about one, three, one, and half a year, respectively.

On the contrary, in the cases of Australia, Greece, Ireland, Portugal, Spain, the UK, and the US, Bohn’s (2007) third proposition would not hold, so no evidence is found on the fulfilment of the nation’s IBC for these countries. Notice, however, that Bohn’s approach gives only sufficiency conditions for sustainability to hold; in other words, if the tests yield positive results this means evidence indicating that the IBC holds, but failure of the tests does not reject it.

4. Conclusions

In this paper, we have tested for the sustainability of external imbalances in the OECD countries over the years 1970-2007 (i.e., before the beginning of the international financial crisis), addressing the recent critique of Bohn (2007) on previous unit root and cointegration tests of the IBC, and allowing for the valuation effects emphasized by Gourinchas and Rey (2007). Unlike Durdu, Mendoza and Terrones (2013), we analyze the case of only those countries undergoing current account deficits in more than half of the years throughout this period, since sustainability should apply to deficits rather than surpluses; and on a country-by-country basis, since panel estimation can hide the different behaviour of specific countries.

Our results show that the three variables net foreign assets, exports of goods and services, and imports of goods and services (augmented with net interest payments and net transfer payments) would be integrated of order one in all the countries analyzed, except for import for Australia (even though at a 10% significance level). Accordingly, the IBC would hold in principle for all of them, with the possible exception of Australia. However, when estimating an error-correction relationship between net exports and net foreign assets, the long-run coefficient had the expected (negative) sign, and was statistically significant, for Austria, Canada, Italy, and New Zealand, so that for these countries the current account deficit would be sustainable. On the contrary, in the cases of Australia, Greece, Ireland, Portugal, Spain, the UK, and the US, no clear-cut results emerge, i.e., the IBC would fail in principle to hold but, since Bohn’s approach gives only sufficiency conditions, a failure of the tests does not mean a rejection of sustainability.

Notice that, in the case of the EU countries that joined the Economic and Monetary Union (EMU) after 1999, the disappearance of the exchange rate risk made easier borrowing in international markets, due

\[ \log(\hat{\rho}) = \log(5) \log(-1) \]

where \( \hat{\rho} \) is the estimate of \( \rho \) in equation (8), from the second column of Table 4.
to both an increase in the supply of funds available and a decrease in their cost. In other words, the allowable external deficit would be higher in a monetary union (Blanchard and Giavazzi, 2002). Even though such an argument certainly softens the practical significance of the external constraint on growth for a country belonging to a monetary union, this should not mean neglecting the size of the external deficit, however. In fact, for these countries, when a structural break was detected (in the cases of Austria, Greece, Ireland and Spain), it appeared quite before 1999 (see Table 2), so no significant change in the behaviour of external imbalances was detected after EMU. This finding could be rationalized on the grounds that the easier financing of external deficits in a monetary union might be offset by the implications of the impossibility of getting a nominal exchange rate depreciation. That is, current account imbalances, while possibly warranted by fundamentals, can also signal elevated macroeconomic and financial disequilibria (Obstfeld, 2012), which now is no longer possible to offset by means of the depreciation of the nominal exchange rate. In other words, in a monetary union, the external constraint would be still binding, and the financing of current account imbalances would not be without limit³.

5. References

³ The role of current account imbalances within a monetary union is discussed at length in Catte (1998).

Sustainability of external imbalances in the OECD countries
