1 **13 Abstract**

2
3
4 14 We investigated the effects of local habitat structure and surrounding landscape
5
6 15 characteristics (proportion of land use types and connectedness) on species density and
7
8 16 composition of bird communities inhabiting [the interior of](#) young tree plantations on
9
10 17 former cropland in central Spain, which were motivated by the Common Agrarian
11
12 18 Policy. Variation of species density (number of species per 0.78 ha) among tree
13
14 19 plantations showed different environmental associations across seasons: local habitat
15
16 20 was more important than landscape characteristics during winter, while they were
17
18 21 similarly important during spring. Species density increased with the development of
19
20 22 the tree layer in winter, and with the presence of urban areas around tree plantations and
21
22 23 cover of the herbaceous layer within them in the breeding season. We identified 15
23
24 24 species that exhibit high relative abundance in woodland habitats within the
25
26 25 Mesomediterranean region of Central Spain that were absent in both seasons in the
27
28 26 studied tree plantations, which were an attractive habitat for urban exploiter species but
29
30 27 an unfavourable habitat for the regional forest species pool except for forest generalist
31
32 28 species. Composition of bird assemblages was more related to local habitat structure
33
34 29 than to landscape characteristics around tree plantations, and was rather similar in
35
36 30 winter and spring seasons. The very different effects of local habitat and landscape
37
38 31 characteristics on bird communities make difficult suggesting management practices
39
40 32 with positive effects for all avifauna species during the entire year. We conclude that the
41
42 33 small size and low maturity of the studied tree plantations do not contribute to
43
44 34 enhancing the bird diversity value of current CAP aids to afforest former cropland with
45
46 35 pines in the Mediterranean region.

1 **39 Introduction**

2
3
4 40 Features of animal assemblages respond to the characteristics of both the local
5
6 41 habitat and the landscape that surround such habitat, and these two sets of
7
8 42 characteristics can interact affecting species composition and abundance (Fischer et al.
9
10
11 43 2011; Geiger et al. 2010; Moreno-Mateos et al. 2011; Piha et al. 2007; Wretenberg et al.
12
13 44 2010). On the other hand, human activities may profoundly modify land cover and
14
15 45 vegetation structure at both levels and, consequently, affect the composition and
16
17
18 46 abundance of local communities (Blondel 1990; Heikkinen et al. 2004).

19
20 47 Large tracts of cropland and pastureland have been reforested in the world in
21
22 48 recent decades by tree plantations or by secondary succession. Seven per cent of the
23
24 49 forest land is tree plantations at present and their annual rate is growing as compared to
25
26 50 afforestation by secondary succession (FAO 2011; Rey Benayas and Bullock 2012).
27
28 51 These tree plantations have noticeable effects on both the abiotic environment and
29
30 52 biological communities (Bremer and Farley 2010; Gómez-Aparicio et al. 2009; Munro
31
32 53 et al. 2009; Poschlod et al. 2005), particularly on birds that are a taxonomic group of
33
34 54 high indicator value (Felton et al. 2010; Lindenmayer et al. 2010; Rey Benayas et al.
35
36 55 2010; Santos et al. 2006). In the European Union, the Common Agrarian Policy (CAP)
37
38 56 has favoured the transformation of farmland into tree plantations since 1993 by means
39
40 57 of a scheme of aid for forestry measures in agriculture (EEC Council Regulation No.
41
42 58 2080/92), which has resulted on the afforestation of ca. 921,210 ha to date (Directorate-
43
44 59 General for Agriculture and Rural Development 2012). This afforestation program
45
46 60 pursues both societal and environmental benefits, including control of erosion,
47
48 61 prevention of desertification, regulation of the water regime, and increasing the fixation
49
50 62 rate of carbon dioxide. The amount of afforested farmland will likely increase in a near
51
52
53
54
55
56
57
58
59
60
61
62
63
64
65

1 63 future in some European regions due to subsidies to vineyard extirpation (e.g. 93,600 ha
2
3
4 64 were extirpated in Spain in the 2008-2011 period of which 73.1% belonged to La
5
6 65 Mancha; Spanish Agrarian Guarantee Fund 2012) together with subsidies to
7
8 66 afforestation of former vineyards, which aim to ensure EU wine production matches
9
10 67 demand and eliminate wasteful public intervention in EU wine markets (Regulation
11
12 68 (EC) 479/2008).

15 69 Cropland afforestations in southern Europe are mostly based on coniferous
16
17 70 species such as *Pinus halepensis* and *P. pinaster*. Afforested fields usually form an
18
19 71 archipelago of man-made woodland habitat in the dominant agricultural matrix. These
20
21 72 plantations may adversely affect open habitat species that are of conservation concern in
22
23 73 Europe, including birds, by replacing high quality steppe habitat and increasing risk of
24
25 74 predation (Cresswell 2008; Díaz et al. 1998; Reino et al. 2010). However, they may
26
27 75 offer opportunities to woodland birds, providing suitable habitats for generalist species
28
29 76 (Rey Benayas et al. 2010). On the other hand, agricultural land abandonment and active
30
31 77 afforestation should not be assumed to always benefit conservation, as it has been
32
33 78 shown for birds of different biogeographic origin in agricultural lands of the
34
35 79 Mediterranean region (increase in diversity with successional stage for Eurosiberian
36
37 80 birds but not for Mediterranean species; Suárez-Seoane et al. 2002). Species-area
38
39 81 relationships for bird communities in natural forests and pine plantations of Spain have
40
41 82 been previously studied in detail (e.g. Díaz et al. 1998; Santos et al. 2006),
42
43 83 demonstrating a very tight relationship between the area of forest islands and species
44
45 84 richness. Nevertheless, little is known about how local species richness at standardized
46
47 85 area units (i.e., species density) is affected by the surrounding landscape while taking
48
49 86 into account habitat characteristics of the focal tree plantation.

1 87 In this study we aim to assess the wintering and breeding bird communities in
2
3
4 88 young tree plantations (<20 years old) motivated by the CAP that are embedded in
5
6 89 Mediterranean agricultural landscapes of Central Spain. These plantations are located at
7
8 90 the south-western limit of the Palaearctic, a region with impoverished woodland
9
10
11 91 avifauna dominated by species of Mediterranean origin and woodland generalists
12
13 92 (Carrascal and Díaz 2003; Monkkonen 1994; Tellería and Santos 1994), and a strong
14
15 93 seasonality in abiotic conditions and productivity that imposes widely different
16
17
18 94 ecological scenarios throughout the year on the communities living in them (Newton
19
20 95 2007). They are established in small patches over a predominantly treeless landscape
21
22
23 96 dominated by herbaceous or woody crops, where large mature forests of holm oaks that
24
25 97 may serve as sources of woodland bird species are very scarce. Therefore, the avifauna
26
27
28 98 in the plantations should be highly influenced by that inhabiting the surrounding
29
30 99 landscape. This biogeographic scenario combined with the current CAP subsidies for
31
32
33 100 afforestation on former arable land allow us testing the importance of local habitat
34
35 101 characteristics and larger-scale features (e.g. the land cover surrounding the tree
36
37
38 102 plantations) on bird assemblages. Moreover, the analysis of the responses of birds that
39
40 103 colonize the interior of these afforestations in two contrasting seasons may
41
42 104 proportionate insights about the temporal generality of their effects and suggest
43
44
45 105 management practices that favour the implementation of friendly afforestation projects
46
47
48 106 for woodland avifauna within deforested landscapes of the Mediterranean region on a
49
50 107 seasonal basis.

51
52 108

53 54 55 109 **Methods**

56 57 110 **Study area**

1 111 Field work was conducted in tree plantations located in Campo de Montiel (La Mancha,
2
3
4 112 situated in the southern Spanish plateau). The study area is ca. 440 km² within UTM
5
6 113 coordinates x_1 4305423, x_2 4272951, y_1 458025 and y_2 483525 (zone 30S; **Figure in**
7
8 114 **Appendix 1**). Altitude ranges between 690 and 793 m a.s.l. The climate is continental
9
10 115 Mediterranean with dry and hot summers and cold winters. Mean annual temperature
11
12 116 and total annual precipitation in the area during the last 30 years were 13.7 °C and 390
13
14 117 mm, respectively (retrieved from <http://www.aemet.es/>). These figures were 16.6 °C
15
16 118 and 359.9 mm in 2011, when our bird surveys took place.

17
18
19
20 119 The area is a representative mosaic of different crops and semi-natural or
21
22 120 introduced woody vegetation that is characteristic of large areas in Mediterranean
23
24 121 landscapes. Croplands were mostly occupied by herbaceous crops (wheat and barley),
25
26 122 harvested once a year in June, and permanent woody crops (olive trees — three to five
27
28 123 meters high, and vineyards — 1 m high). Natural vegetation mostly consisted of holm
29
30 124 oak *Quercus rotundifolia* L. woodland and riparian forests that have been mostly
31
32 125 extirpated from this region. Until 1992, woodland cover was restricted to open holm oak
33
34 126 patches, usually grazed by sheep and goats. However, as in many other Mediterranean
35
36 127 landscapes, the agricultural land is subjected to intensive management (e.g., irrigation of
37
38 128 vineyards and olive groves) and land use change. A major result of land use change is
39
40 129 the abandonment of herbaceous cropland and vineyard extirpation and their
41
42 130 afforestation with the native Aleppo pine *Pinus halepensis* Mill. alone or mixed with
43
44 131 holm oak and *Retama sphaerocarpa* (L.) Boiss., which has increased forest land in the
45
46 132 last 20 years. These tree plantations are noticeably dominated by pines as they establish
47
48 133 better and grow faster than the other planted species. Thus, height and diameter at breast
49
50 134 height (dbh) of dominant pines are surrogates of the age of tree plantations.
51
52
53
54
55
56
57
58
59
60
61
62
63
64
65

1 135
2
3
4 136 Bird survey
5
6 137 First, all young forest plantations in the study area were identified using both orto-
7
8 138 photos (Geographic Information System of Farming Land 2010; hereafter SigPac) and
9
10
11 139 Google Earth®, and were later verified in the field. We found 99 plantations that were
12
13 140 established in 1992 or later. Next, we selected the plantations to be surveyed for birds,
14
15 141 excluding those smaller than 1 ha: 61 forest plantations with a mean area of 4.82 ha (sd
16
17
18 142 = 5.61; larger plantation = 36.5 ha). Average spacing distance between [studied](#)
19
20
21 143 plantations was 11.7 km (see Figure 1 in Appendix 1). Pruning and thinning are the
22
23 144 management practices performed on these plantations that modify their vegetation
24
25 145 structure; 26 of our surveyed plantations were pruned, 16 of which were also thinned.
26
27
28 146 Species abundance and density were quantified by means of circular plot
29
30 147 censuses that were carried out in winter (January and February) and spring (April and
31
32 148 May) 2011, to study wintering and breeding bird communities, respectively. Every tree
33
34
35 149 plantation was represented by one circular plot located at the centre of the plantation.
36
37
38 150 Census method consisted of point-counts (Bibby et al. 2000), ten minutes long each,
39
40 151 recording all birds detected visually and/or acoustically within the 50-m radius plot
41
42 152 (0.78 ha). We noted the presence of every bird species during the 10 minutes except if
43
44
45 153 individuals were over-flying the plot. Two censuses of each plot were carried out in
46
47 154 each season, one in the morning between sunrise and 3 hours later and one in the
48
49
50 155 evening two hours before sunset. The relative abundance of each species and local
51
52 156 species density ([i.e., number of species per 0.78 ha](#)) were estimated using the average of
53
54
55 157 the two censuses in each season. The small area covered by the plots, and the relatively
56
57 158 long time devoted to bird counts (accumulated census time of 20 minutes in each
58
59
60
61
62
63
64
65

1 159 season), maximizes the detection probability of species within the area of 0.78 ha and,
2
3
4 160 thus, the accurate estimations of local species density and abundance (Shiu and Lee
5
6 161 2003). This time invested in bird census (25.6 min ha⁻¹) is considerably longer than that
7
8 162 used in previous studies recording species richness in woodland islands (e.g., 10.2 min⁻¹
9
10
11 163 in pine plantations sampled by Díaz et al. 1998). Otherwise, our purpose was not to
12
13 164 exhaustively characterize the avifauna of each plantation, but to analyze the variation of
14
15 165 local species density in the interior of this novel habitat of an archipelago of young and
16
17
18 166 small afforestations that punctuates the agricultural landscape. All censuses were
19
20 167 conducted by the same well trained field ornithologist (JS S-O) on windless and rainless
21
22
23 168 days.

24
25 169 To have a reference of the avifauna that potentially can colonize the studied
26
27
28 170 plantations, we used the habitat breadth of the bird species in 15 main habitat categories
29
30 171 as well as their relative abundance in woodlands within the Mesomediterranean region
31
32 172 of Central Spain obtained from Carrascal and Palomino (2008).

33
34
35 173
36
37
38 174 Local habitat and landscape variables

39
40 175 We characterized two sets of variables related to tree plantations, namely (i) local
41
42 176 habitat variables, which included vegetation in the bird census plots and area of the
43
44
45 177 plantations, and (ii) landscape variables, which included tree plantation connectivity and
46
47 178 land use around plantations.

48
49 179 (i) Vegetation structure and composition of main plant species at each surveyed
50
51
52 180 forest plantation were measured in a 25-m radius plot and a 10-m radius plot that
53
54 181 coincided with the centres of the bird census plots. This sampling was carried out before
55
56
57 182 the spring bird census. In the 25-m radius plots, we directly counted or estimated by

1 183 eye, after previous training, the following structural features of the vegetation:
2
3 184 percentage cover of chamaephytes, shrubs and trees, average height of chamaephytes,
4
5 185 shrubs and trees, and number of trunks <5, 5-10, 10–20, 20–40 and >40cm in dbh. In
6
7
8 186 the 10-m radius plots, we estimated percentage cover of herbs and bare soil and
9
10
11 187 measured the average height of the herb layer. All vegetation measurements (**Table 1**)
12
13 188 were carried out by the same observer (JS S-O) to avoid inter-personal bias.

14
15
16 189 (ii) Land use types were identified by means of land use layers taken from
17
18 190 SigPac (see source above). They were analyzed with ArcGIS 10.0 in 1-km buffer-
19
20
21 191 rings from the center of each forest plantation; on each buffer-ring, the percentage of
22
23 192 area occupied by each land use type was obtained, resulting in the figures shown in
24
25 193 **Table 1**. Finally, for a target plantation, structural connectedness was measured as the
26
27 194 average distance of the three closest plantations or natural woodland patches weighted
28
29 195 by the area of such plantations or woodland patches (**Table 1**).

30
31
32
33 196

34 35 197 Statistical analyses

36
37 198 The effects of pruning on the development of the tree layer was tested by means of a
38
39
40 199 MANOVA on percentage of tree cover, height of the tree layer, dbh, and number of
41
42 200 trunks > 5 cm.

43
44
45 201 The relationships of species density and species [composition with](#) local habitat
46
47 202 and landscape predictor variables, were separately analysed for the winter and the
48
49
50 203 breeding season by means of Partial Least Squares Regressions (hereafter PLSR; Abdi
51
52 204 2007). Sample units for these analyses were the 61 census plots in the tree plantations.
53
54 205 Results obtained with PLSR are similar to those from conventional multiple regression
55
56
57 206 techniques; however, PLSR allows for the simultaneous analysis of multiple response
58
59

1 207 variables, and it is extremely robust to the effects of low sample size (i.e. overfitting)
2
3
4 208 and high degree of correlation between predictor variables (i.e. severe multi-
5
6 209 collinearity) (Carrascal et al. 2009). PLSR establishes associations between the response
7
8 210 variables and factors extracted from the predictor variables that maximize the explained
9
10
11 211 variance in the response variables. These factors are defined as linear combinations of
12
13 212 predictors, so the original multidimensionality is reduced to a lower number of
14
15 213 orthogonal factors to detect structure in the relationships between predictor variables
16
17
18 214 and between these factors and the response variables. The relative contribution of each
19
20
21 215 predictor to the extracted factors was calculated by means of the square of predictor
22
23 216 weights. The PLSR components regarding species composition were obtained based on
24
25 217 the abundance of those species with >0.1 birds/census plot; the abundance of 12 species
26
27
28 218 in winter and 17 species in spring defined the response variables that were summarized
29
30
31 219 in composition components by means of the linear combination of the species'
32
33 220 abundances. Only those components significant after a ten-fold validation procedure
34
35 221 were retained (StatSoft 2011).

36
37
38 222 All statistical analyses were conducted in Statistica 10 (StatSoft 2011).

39
40 223

41 42 224 **Results**

43 44 225 Tree plantation and landscape characteristics

45
46
47 226 There was a broad variation in the local habitat variables of the studied tree plantations
48
49
50 227 (**Table 1**). Overall, the number of pines >5 cm dbh was not too large but there were a
51
52 228 lot of small trees when considering the average trunk diameter of pines. Pruning
53
54
55 229 enhanced the development of the tree layer according to a MANOVA (Wilk's $\lambda =$
56
57 230 0.752, $p = 0.003$, $n = 61$).

1 231 There was also a considerable variation in the landscape characteristics around
2
3
4 232 the tree plantations in an area mainly dominated by dry herbaceous cropland, olive tree
5
6 233 groves and vineyards (**Table 1**).
7
8 234
9
10
11 235 Species density
12
13 236 Average number of species per census plot of 0.8-ha did not significantly change
14
15 237 between seasons (paired t-test: $t = 0.158$, d.f. = 60, $p = 0.875$), being 4.38 species during
16
17 238 winter time (range = 0 - 9, sd = 2.02, n = 61 plots) and 4.43 species during the breeding
18
19 239 season (range = 1 - 10, sd = 1.84). Winter and spring species density were not
20
21 240 significantly correlated ($r = 0.208$, $p = 0.109$, n = 61).
22
23
24

25 241 One significant component ($p \ll 0.001$) was obtained in each PLSR analysis of
26
27 242 the number of species in the 61 studied tree plantations using all local habitat and
28
29 243 landscape predictor variables, accounting for 31.9% and 31.4% of total variance in
30
31 244 winter and breeding season species density, respectively (**Table 2** and **Figure 1**).
32
33 245 Environmental effects on local species density were very different in both seasons. The
34
35 246 weights of local habitat and landscape variables were not significantly correlated in
36
37 247 winter and spring ($r = 0.190$, $p = 0.372$, n = 24 predictor variables), thus defining
38
39 248 different patterns of environmental determinism on species density in both seasons.
40
41
42
43
44

45 249 In winter, species density mainly increased with the development of the tree
46
47 250 layer (cover, height and trunk diameter of pines), which was associated to low
48
49 251 development of the herbaceous and shrub layers (**Table 2** and **Figure 1**). None
50
51 252 predictor variable describing landscape characteristics around the plantations attained a
52
53 253 |weight| > 0.2. Thus, the importance of local habitat variables on winter species density
54
55 254 was considerably higher than the importance of variables describing the landscape
56
57
58
59
60
61
62
63
64
65

1 255 characteristics (calculated by means of the square of predictor weights), and was
2
3
4 256 considerably higher than that expected considering the relative number of predictors in
5
6 257 the two groups of variables (local habitat = 0.86, landscape = 0.14; the ‘null’
7
8 258 proportions according to the number of predictors was 0.38 for nine local habitat
9
10 259 variables and 0.62 for 15 landscape variables).

13 260 During the breeding season, species density was positively associated with the
14
15 261 presence of waste lands, urban areas and scattered buildings around them, and
16
17 262 negatively related to their size, the height and cover of shrubs and the amount of area
18
19 263 around plantations covered by woodland (mainly remaining patches of holm oak
20
21 264 forests), fruit groves, shrubland and dry herbaceous cropland (**Table 2** and **Figure 1**).
22
23 265 Landscape characteristics of the surrounding the tree plantations were similarly
24
25 266 important than local habitat in determining species density during the breeding season
26
27 267 (summatory of the square of predictor weights: 0.42 for nine local habitat variables and
28
29 268 0.58 for 15 landscape characteristics, which were very similar to the ‘null’ proportions
30
31 269 of 0.38 and 0.62 respectively, according to the number of predictors).
32
33
34
35
36

37 270

40 271 Species composition

42 272 The avifauna was dominated by the great tit (*Parus major*), the chiffchaff (*Phylloscopus*
43
44 273 *collybita*), the goldfinch (*Carduelis carduelis*), the wood pigeon (*Columba palumbus*)
45
46 274 and the magpie (*Pica pica*) in wintertime, and by the goldfinch, the spotless starling
47
48 275 (*Sturnus unicolor*), the wood pigeon and the magpie during the breeding season (spring)
49
50 276 (average of more than one detected individual per census plot in both seasons;
51
52
53 277 **Appendix 2**).

1 278 The following species that exhibit high relative abundance in woodland habitats
2
3
4 279 within the Mesomediterranean region of Central Spain according to Carrascal and
5
6 280 Palomino (2008) were completely absent in both seasons in the studied tree plantations:
7
8 281 great spotted woodpecker (*Dendrocopos major*), blackbird (*Turdus merula*), nuthatch
9
10 282 (*Sitta europaea*), short-toed treecreeper (*Certhia brachydactyla*), firecrest (*Regulus*
11
12 283 *ignicapillus*), coal tit (*Periparus ater*), crested tit (*Lophophanes cristatus*), long-tailed tit
13
14 284 (*Aegithalos caudatus*), hawfinch (*Coccothraustes coccothraustes*), blue tit (*Cyanistes*
15
16 285 *caeruleus*), rock bunting (*Emberiza cia*), jay (*Garrulus glandarius*), and Eurasian
17
18 286 Hoopoe (*Upupa epops*). Similarly, other woodland species in the region such as robin
19
20 287 (*Erithacus rubecula*) and Woodchat Shrike (*Lanius senator*) were very scarce in the
21
22 288 studied plantations.

23
24
25
26
27
28 289 Relative abundances of species across the 61 studied tree plantations were not
29
30 290 tightly correlated among themselves either in winter or during the breeding season, as
31
32 291 defined by the low variance attained by the first components of the PLSRs in both
33
34 292 seasons using the common species (those with more than 0.1 birds/plot): 7.9% of
35
36 293 variance in the relative abundances of 12 species in winter, and 5.7% of variance for 17
37
38 294 species in spring. Nevertheless, these loose patterns of co-variation in species
39
40 295 abundances were highly associated with the plantation characteristics, mainly local
41
42 296 habitat in both seasons (see below): $r = 0.675$, $p \ll 0.001$ for winter, and $r = 0.700$, p
43
44 297 $\ll 0.001$ for the breeding season.

45
46
47
48
49 298 The main pattern of co-variation in species abundances during the winter season
50
51 299 was the association of the chiffchaff, great tit, magpie, wood pigeon, chaffinch
52
53 300 (*Fringilla coelebs*), and goldfinch in tree plantations with a well developed tree layer
54
55 301 (**Figure 2**; see predictor variable weights in Table 2; these species were selected
56
57
58
59
60
61
62
63
64
65

1 302 according to absolute values of loadings > 0.2 in the component of species abundances).
2
3
4 303 On the other hand, there is a common pattern of increase in species abundances during
5
6 304 the breeding season that associates the magpie, great tit, and wood pigeon in tree
7
8 305 plantations with a tall and dense cover of the tree layer surrounded by relatively high
9
10 306 cover of vineyard with olive trees, as opposed to the co-variation of abundances of rock
11
12 307 pigeon (*Columba livia*), spotless starling, little bustard (*Tetrax tetrax*) and crested lark
13
14 308 (*Galerida cristata*) in plantations with high cover of the shrubs and herb layers near
15
16 309 urban areas (**Figure 2**).

17
18
19
20 310 The importance of the environmental factors related to composition of bird
21
22 311 assemblages was rather similar in winter and spring (**Table 2**), as the weights of local
23
24 312 habitat and landscape variables were highly correlated in both seasons: $r = 0.921$, $p \ll$
25
26 313 0.001 , $n = 24$ predictor variables). Moreover, the importance of local habitat variables in
27
28 314 defining the co-variation of abundance of bird species was considerably higher than that
29
30 315 of variables describing the landscape characteristics around tree plantations in both
31
32 316 seasons calculated by means of the square of predictor weights (WINTER: local habitat
33
34 317 = 0.83 , landscape = 0.17 ; SPRING: local habitat = 0.73 , landscape = 0.27 ; the ‘null’
35
36 318 proportions according to the number of predictors were 0.38 and 0.62 , respectively).
37

319

320 **Discussion**

321 Overall community composition

322 Our results show that the local composition of bird assemblages **inhabiting the interior**
323 **of young Mediterranean cropland afforestations** are characterized by a few common
324 dominant species, namely magpie, wood pigeon and goldfinch in both seasons, great tit
325 and chiffchaff in wintertime, and spotless starling in spring. These ubiquitous species

1 326 are generalist birds of wooded areas, with broad geographical ranges and high
2
3
4 327 population sizes in Spain (Carrascal and Palomino 2008; Martí and del Moral 2003).
5
6 328 They are of little conservation concern in the European context (BirdLife International
7
8 329 2004). They are also of little sensibility to habitat fragmentation as they can thrive in
9
10
11 330 very small woodland patches (Díaz et al. 1998; Razola and Rey Benayas 2009; Santos
12
13 331 et al. 2002), such as those corresponding to the afforestations investigated in this study.

14
15
16 332 The biogeographical basis of the avifauna in this Mediterranean region, with an
17
18 333 impoverished European forest avifauna dominated by species of early successional
19
20 334 stages, probably limits the possibility of colonization of pure coniferous woodland
21
22 335 species. Forest specialists of Mediterranean coniferous forests that require more mature
23
24 336 and larger woodland patches (Díaz et al. 1998; Santos et al. 2006), such as the great
25
26 337 spotted woodpecker, firecrest, crested tit, short-toed treecreeper or nuthatch, were never
27
28 338 recorded in these plantations, thus emphasizing the low suitability of these woodlands
29
30 339 for forest avifauna of the region. This points to the importance of the biogeographic
31
32 340 context when designing restoration plans with afforestations in agricultural-dominant
33
34 341 landscapes (Suárez-Seoane et al. 2002), and enlightens the conflicts that can arise if
35
36 342 single services of ecological restoration such as carbon sequestration by tree plantations
37
38 343 are targeted without taking into account regional biodiversity (Bullock et al. 2011).

39
40
41
42
43
44
45 344

46
47 345 Relative effects of local habitat and landscape characteristics

48
49 346 The influence of different sets of environmental factors, namely local habitat of tree
50
51 347 plantations and landscape characteristics, on bird communities changed considerably
52
53 348 between seasons, with a prominent role of local habitat variables during winter for
54
55 349 species density, and a more balanced importance of landscape characteristics around
56
57
58
59
60
61
62
63
64
65

1 350 plantations and local habitat during the breeding season. During the breeding season
2
3
4 351 birds are spatially restricted to the focal place where they breed, and thus they show
5
6 352 marked habitat preferences related to vegetation structure, which is an important
7
8 353 attribute determining species composition of bird communities at the local scale
9
10
11 354 (Hinsley et al. 2009; Hurlbert 2004). In contrast, during the winter period, birds adopt a
12
13 355 vagabonding life-style exploring a greater variety of habitats over larger areas to track
14
15 356 the spatial and temporal distribution of food availability (Levey and Stiles 1992;
16
17
18 357 Wiktander et al. 2001). From this perspective, local habitat should have a greater
19
20 358 importance in the breeding season than in the winter in influencing bird communities of
21
22
23 359 tree plantations within agricultural landscapes. Nevertheless, our results do not support
24
25 360 this prediction for species density.

27
28 361 The negative influence of the area of tree plantations studied here on local
29
30 362 species density is related to the fact that the probability of recording “ubiquitous/edge”
31
32 363 bird species in the centre of plantations decreases as plantation area increases. This
33
34
35 364 result, together with the remarkable negative influence of nearby woodlands on local
36
37
38 365 species density in the interior of the plantations, reinforces the idea of the low
39
40 366 favourability of these young afforestations dominated by pines for the forest avifauna of
41
42 367 the study region, especially if they are large.

44
45 368 The high importance of urban cover around the tree plantations on species
46
47 369 density during spring points to the attractiveness of scarce woodland fragments to
48
49 370 urban-exploiters of Central Spain (Palomino and Carrascal 2006), such as the rock dove
50
51 371 (*Columba livia*), collared dove (*Streptopelia decaocto*), greenfinch (*Carduelis chloris*),
52
53
54 372 house sparrow (*Passer domesticus*), magpie, or spotless starling. It also emphasizes that
55
56
57 373 urban development extends its impact on the surrounding habitats affecting bird
58
59
60
61
62
63
64
65

1 374 communities, especially by the influence of just a few very common urban species (e.g.
2
3 375 Findlay and Houlahan 1997; Odell and Knight 2001; Palomino and Carrascal 2007;
4
5 376 Sauvajot et al. 1998). Urban and surrounding areas are a source of the ubiquitous and
6
7 377 opportunistic nest predator magpie, and could thus entail additional conservation
8
9 378 concern, because its overabundance around the cities could pose a deleterious effect on
10
11 379 other bird species breeding in the plantations (e.g. Andren 1992; Groom 1993; Paradis
12
13 380 et al. 2000). Similarly, Lindenmayer et al. (2012) found that another aggressive corvid
14
15 381 reduced bird abundance in Australian tree plantations located in an agricultural
16
17 382 landscape.

18 383

19 384 Management of tree plantations

20 385 The results of this study show that, overall, there are difficulties in making
21
22 386 generalizations about the environmental factors that determine bird diversity inhabiting
23
24 387 [the interior of](#) young tree plantations in Mediterranean agricultural landscapes on a year-
25
26 388 round basis, and thus in outlining management recommendations to make them
27
28 389 friendlier for the avifauna. These plantations offer opportunities for a few generalist
29
30 390 forest bird species but are not perceived as an attractive breeding habitat for most forest
31
32 391 species in the region. Further, the youngest plantations with under-developed tree layer
33
34 392 and presence of shrub and herbaceous layers benefit bird species that are characteristic
35
36 393 of open farmland habitats such as the calandra lark, little bustard and rock pigeon (Rey
37
38 394 Benayas et al. 2010). As pruning of pines speeds up the development of the tree layer, a
39
40 395 more generalized use of this practice would increase overall species density in winter
41
42 396 and benefit forest species such as the wood pigeon, which is of interest to hunters, and
43
44 397 insectivorous birds such as the great tit or blue tit, which have the potential of

1 398 enhancing pest regulation in both tree plantations and crops around them (Jedlicka et al.
2
3 399 2011).

4
5
6 400

7
8 401 **Conclusions**

9
10 402 Local habitat and surrounding landscape characteristics in Mediterranean landscapes
11
12 403 dominated by croplands had very different effects on bird communities inhabiting [the](#)
13
14 404 [interior of](#) young afforestations in the winter and breeding seasons, which make difficult
15
16 405 suggesting extensive management practices with positive effects for all avifauna species
17
18 406 during the entire year. These small, monotonous plantations are an attractive habitat for
19
20 407 urban exploiter species but an unfavourable habitat for the regional forest species pool
21
22 408 with the exception of the forest generalist species. Therefore, the small size and low
23
24 409 maturity of the studied tree plantations do not contribute to enhancing the bird diversity
25
26 410 value of current CAP aids to afforest former cropland with pines in the Mediterranean
27
28 411 region. Further monitoring of bird communities as these plantations get older is
29
30 412 necessary to provide more robust science-based management recommendations, and test
31
32 413 the success of the implemented recommendation (more use of tree pruning) that the
33
34 414 results of this study hinted.

35

Table 1. Mean, standard deviation (sd) and range (min / max) of the local habitat and landscape variables describing the characteristics of the 61 studied tree plantations.

	mean	sd	Range	
Local habitat				
Area of tree plantation (ha)	4.8	5.6	1.0	36.5
Cover of the tree layer (%)	35.4	25.5	1.7	100
Average pine height (m)	3.5	1.5	0.9	7.2
Average trunk diameter of pines (dbh cm)	11.4	5.8	0	33.2
# of pine trunks larger than 5 cm dbh / 0.2 ha	70.5	50.7	0	185
Cover of the shrub layer (%)	4.7	8.8	0	46.2
Average height of the shrub layer (m)	1.2	1.1	0	3.3
Cover of the herbaceous layer (%)	54.3	40	0	100
Average height of the herbaceous layer (m)	0.4	0.3	0	1.1
Landscape around plantations				
Average distance to other woodlands (m)	739.7	621.7	14	2506
Streams, rivers and lagoons (% cover)	0.7	1.1	0	4.1
Roads and rural tracks (% cover)	6.4	5.2	0	31.1
Woodlands (% cover)	4.2	4.7	0.1	25.2
Fruit groves (% cover)	1.1	1.3	0	5.4
Waste lands (% cover)	6.8	4.4	0	14.8
Olive groves (% cover)	21.9	23.7	0	94.7
Pastures with scattered trees (% cover)	0.4	1.6	0	9.4
Scrubland (% cover)	10.0	7.4	0	29.5
Pastures (% cover)	1.1	3.2	0	19.1
Dry herbaceous cropland (% cover)	18.2	9.2	0	40.8
Vineyards (% cover)	20.9	13.7	0	49.2
Vineyards with olive trees (% cover)	5.1	8.5	0	32.3
Dried fruit orchards (% cover)	0.6	2.4	0	16.9
Urban areas and scattered buildings (% cover)	2.4	4.2	0	25.8

Table 2. Results of the partial least squares regression (PLSR) models analyzing the variation in bird species density and bird species composition in 61 tree plantations during winter and the breeding season (spring) according to nine local habitat features of plantations and 15 landscape predictor variables. Figures shown are the predictor weights of each variable in each component (in bold those with $|\text{weights}| > 0.2$; this threshold was calculated according to the following equation: $[1 / \#\text{predictors}]^{0.5}$).

	SPP DENSITY		SPP COMPOSITION	
	Winter	Spring	Winter	Spring
Local habitat				
Area of tree plantation (ha)	0.16	-0.29	0.02	0.01
Cover of the tree layer (%)	0.39	0.09	0.42	0.41
Average pine height (m)	0.47	0.12	0.45	0.45
Average trunk diameter of pines (dbh cm)	0.41	-0.03	0.34	0.29
# of pine trunks larger than 5 cm dbh	0.41	-0.09	0.41	0.33
Cover of the shrub layer (%)	-0.06	-0.39	-0.16	-0.16
Average height of the shrub layer (m)	-0.22	-0.34	-0.28	-0.23
Cover of the herbaceous layer (%)	-0.10	0.19	-0.08	-0.21
Average height of the herbaceous layer (m)	-0.25	-0.03	-0.26	-0.20
Landscape around plantations				
Average distance to other woodlands (m)	-0.06	0.08	0.07	0.14
Streams, rivers and lagoons (% cover)	0.08	-0.03	0.00	0.06
Roads and rural tracks (% cover)	0.17	-0.06	0.03	0.01
Woodlands (% cover)	-0.01	-0.29	-0.14	0.00
Fruit groves (% cover)	-0.15	-0.34	-0.12	-0.11
Waste lands (% cover)	0.01	0.27	-0.04	-0.17
Olive groves (% cover)	-0.07	0.08	-0.01	0.10
Pastures with scattered trees (% cover)	0.02	0.08	0.08	-0.04
Scrubland (% cover)	0.04	-0.33	-0.04	-0.04
Pastures (% cover)	0.01	0.02	0.08	-0.01
Dry herbaceous cropland (% cover)	-0.06	-0.20	-0.08	-0.11
Vineyards (% cover)	0.07	0.05	0.01	-0.04
Vineyards with olive trees (% cover)	0.06	0.19	0.19	0.22
Dried fruit orchards (% cover)	0.18	-0.13	0.21	0.09
Urban areas and scattered buildings (% cover)	-0.18	0.26	-0.16	-0.35

Figure 1. Relationship between (a) the species density per 0.8-ha census plot of tree plantations in the winter (top) and (b) the breeding season (down) and the multivariate gradient (first PLSR component) defined by the Partial Least Squared Regression analysis on 9 local habitat and 15 landscape predictor variables.

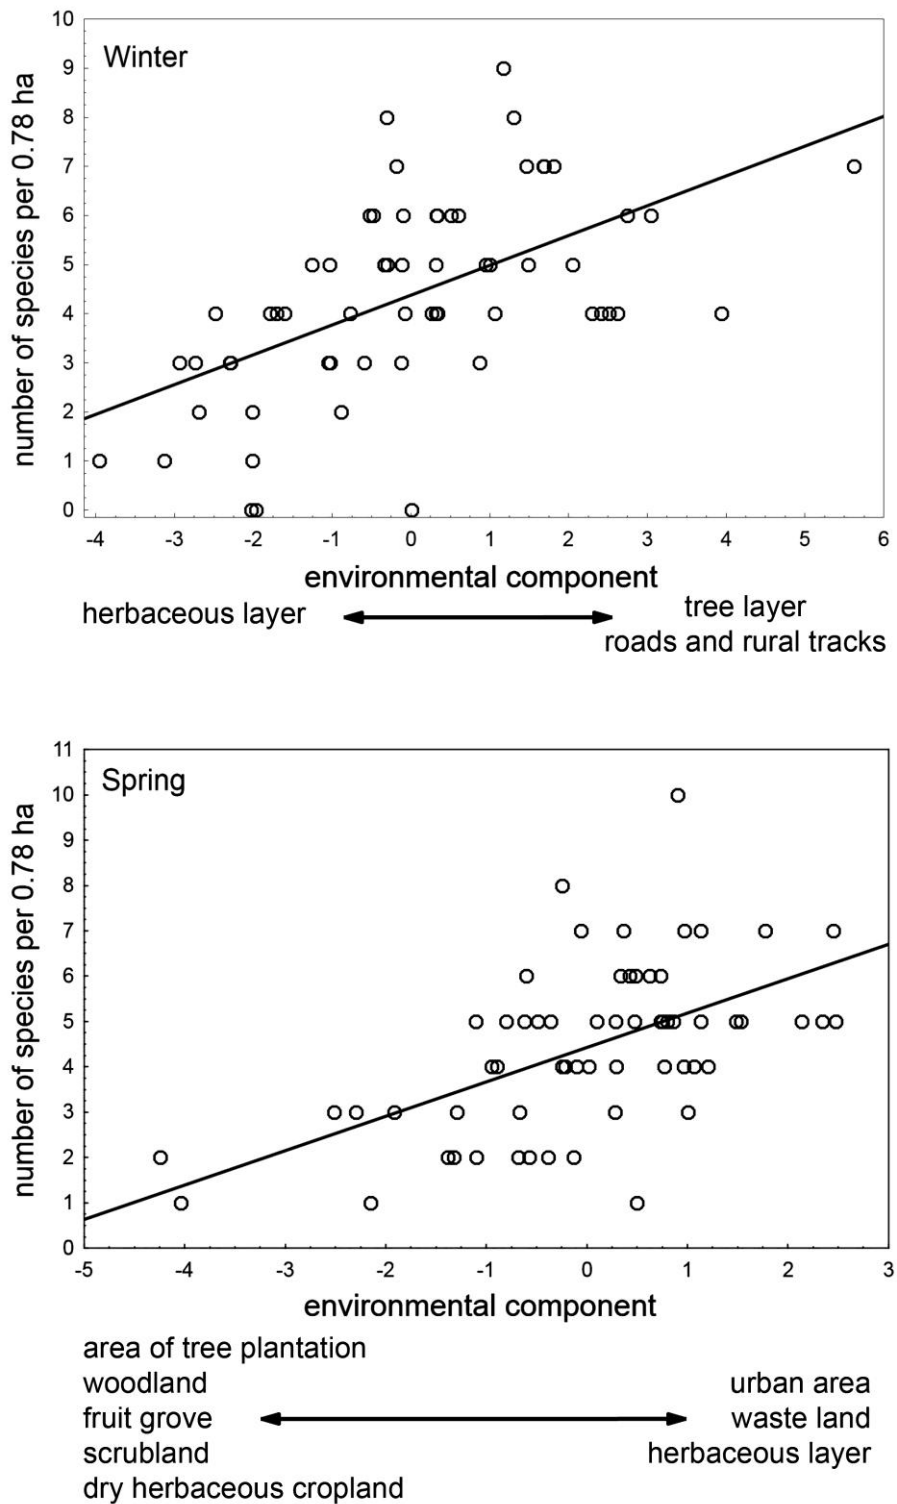

Figure 2. Relationship between (a) the species composition of tree plantations in the winter (top) and (b) the breeding season (down) and the multivariate gradient (first PLSR component) defined by the Partial Least Squared Regression analysis on 9 local habitat and 15 landscape predictor variables.
